Foreword

University of Yangon (UY) makes an all-out effort to be a leading higher educational institution in Myanmar as a Flagship university on par with regional counterparts and in line with international trends. UY therefore expands the frontiers of knowledge by developing research culture.

UY created a research-teaching nexus namely Universities' Research Centre (URC-UY) where research informs and enhances teaching agenda. University education is fundamentally about how to solve problems based on data and/or logical thought. Those involved in research are better at imparting these skills to students with inquiring minds. The Korea Foundation for Advanced Studies (KFAS) has been supporting research activities in UY through the Asia Research Centre (ARC-UY). To a researcher in UY, ARC-UY and URC-UY should be seen as two sides of the same coin in much the same way as financial support and research activity should be regarded.

Research is only meaningful if it is communicated, so the research outcomes must be published and contribute to the body of knowledge; even better if research outcomes can be impactful through commercialization or implementation. This journal proudly presents 15 research papers resulted from the outstanding research projects carried out by the academic departments of UY.

I would like to express my appreciation and congratulations on the concerted effort of the researchers who have made a great deal of excellent contribution to this issue. I also would like to to express my heartfelt thanks to Mr. Park In-Kook,President of the KFAS for his continued support to the ARC-UY.

Abstract

Solar energy is available almost everywhere and solar power is very helpful in our everyday life. The plane of PV panel should always be normal to the incident solar rays to get maximum energy. The seasonal movement of the earth affects the radiation intensity received on the PV panel. Solar tracking systems can effectively improve energy efficiency of a solar PV panel. This research aimed to obtain maximum possible power from a solar panel all day long when the panel tracks the sun and rotates through the axis. This movement was achieved by installing a couple of servo motors with the solar panel that changes its direction according to the positioning of the sun. Arduino UNO with ATmega328p microcontrollers have been used for this purpose. It receives sensor output signal and controls servo motors according to the assigned program. One servo motor moves the panel vertically to upward and downward while the other moves the panel horizontally from left to right direction. Since the maximum solar ray is fallen down on the solar panel module, the maximum power output can be achieved from the module.

Keywords: Arduino UNO; dual axis; LDR, prototype; servo motor; solar tracking

I. Introduction

Global energy consumption is dramatically increasing due to higher standard of living and the increasing world population. The world has limited fossil and oil resources. As a consequence, the need for renewable energy sources becomes more urgent. The green energy, also called renewable energy, has gained much attention nowadays [Tiberiu, T., and Liviu, K., 2010]. Solar energy is one of the primary sources of clean, abundant and inexhaustible energy that not only provides alternative energy resources, but also improves environmental pollution. The most immediate and technologically attractive use of solar energy is through photovoltaic conversion [Morega, A. M. and Bejan, A., 2005]. Solar tracker is an automated solar panel that actually follows the Sun to increase the power. Solar tracking is the most appropriate technology to enhance the electricity production of a PV system [Abigail, K., 2007].

In this work, the solar tracker system with two axes has been designed and implemented by using four LDRs and two Tower Pro (MG90S) motors with gear arrangements. In order to get the maximum efficiency, the solar tracker with two axes sense the direct solar radiations falling on photo-sensors as a feedback signals [Akposionu, K. N., 2012]. The control algorithm has been implemented via Atmega 328p microcontroller on a simple and cheap mechanical structure.

II. Designing a Prototype Dual Axis Solar Tracker

In the first step, a block diagram for a prototype dual axis solar tracker was designed as illustrated in Figure 1. The layout plan of the prototype dual axis solar tracker
