

Diversity of Fish Species in Nat Min Chaung In, Singu Township

Cho Sin Win¹, Than Htwe², Thant Zin³

Abstract

The study was carried out in Nat Min Chaung In from July, 2015 to January 2016 to evaluate the species richness and diversity of fish fauna related to water physiochemical parameters. Collection of data was performed bimonthly. Data were analyzed by Margalef (1958), Simpson (1949), Shannon-Wiener (1949) and Hill (1973). A total of 39 species belonging to 27 genera, 16 families and eight orders were recorded in the study area. The order Cypriniformes (38.46%) was found to be the highest inspecies composition. Among the species recorded, *Corica soborna* was dominant species. The value of Marglef's richness index, d (3.8165) was the highest in August. The values of Simposon's index D (0.0815), Shannon-Weiner's index H' (2.7879), Hill diversity indices N_1 (16.0995), N_2 (12.2727) were recorded during November. The highest evenness value E (0.8046) was found in January. According to the value of physiochemical parameter of water in the study area, the maximum depth of water 13.5 m in July and the minimum 4.5 m in January were found. The highest value of water temperature (32.5°C) was observed in July and the lowest value of water temperature (21.4°C) was recorded in December. pH ranged from 7.4 in August to 8.2 in November. Dissolved oxygen ranged from 3.8 mg/L in September to 6.8 mg/L in November. The monthly variation of physiochemical parameters of water quality in the study area directly influenced on the composition, richness and diversity of fish fauna. Based on the result of study, it may be concluded that the richness of fish fauna and species diversity is useful for implementing conservation strategies in order to maintain the sustainability of fisheries in Nat Min Chaung In.

Keywords: Nat Min Chaung In, fish, species, diversity indicies, physiochemical parameters

Introduction

Biodiversity is also essential for stabilization of ecosystems, protection of overall environmental quality, for understanding intrinsic worth of all species on the earth. Species diversity is a property at the population level while the functional diversity concept is more strongly related to ecosystem stability and stress, physical and chemical factors for determining population dynamics in the lentic ecosystem. Fish constitutes almost half of the total number of vertebrates in the world. They live in almost all conceivable aquatic habitats. They exhibit enormous diversity of size, shape and biology, and in the habitats they occupy (IUCN, 2009).

The fish diversity is correlated with biological and various physiochemical parameters that regulate the productivity and distribution of different species of the fishes. The fish population is abundant and majority of fishes are exploited for human consumption (Bakawale and Kanhere, 2013). The rich diversity of fish (25000 species) is due to the diversity of aquatics and the range of water quality in which they live. It also results from immerse isolation in time and space. Fish diversity has been reduced by habitat loss, siltation, water pollution, dams, mining, and human development (Helfrich and Neves, 2009).

Macro habitat assessment indicated that high habitat diversity was associated with high species diversity and that habitat volume was a major determining factor for species diversity and abundance (Arunachalam, 2000).

³ Professor and Head, Dr., Department of Zoology, University of Mandalay

Habitat destruction and the introduction of exotic species are causing the extinction of many native species (Sax and Gaines, 2003).

Species diversity indices are influenced by both the species number, or "richness", and the species "evenness", or relative number of individuals of a species in a given habitat (Koenig *et al.*, 1976). Species diversity of aquatic organisms in flood plains connected with large river is always large, because they can easily recolonize the flood plain from the main river channel and other permanently aquatic habitats (Kar *et al.*, 2006).

Nat Min Chaung In is the most popular In due to richness in fishes fauna. It is also situated near Taung In village at the southern part of Singu Township. The In lies on the east of the Ayeyarwady River. It is connected by Zeikchaung creek which joins the Ayeyarwady River. It is a long narrow channel about 4.83 km in length, 6.1 - 9.1 m in wide and 4.6 - 12.2 m depth, between Saw Lu In, and Myaung Katku In. Although Nat Min Chaung In is a seasonal flood plain leasable fishery, the In has no basic biological information of fish species. Therefore, the present study was conducted to evaluate the fish diversity in relation to physiochemical parameter of water quality of Nat Min Chaung In and to contribute a better knowledge for conservation management of aquatic environments.

Materials and Methods

Study Site

The study site was selected in Nat Min Chaung In near Taung In village that is situated in the southern part of Singu Township, 22° 29' 29.95" N and 96°01' 03.78"E.

Study Period

The present study was conducted from July 2015 to January 2016.

Fig.1 Location map of study area (Source: Google Map)

Collection of Specimens

Specimen was collected bimonthly from the study site with the help of local fishermen and In owner. The morphological characters and measurements of each species were noted down and taken the photo immediately before the body color disappeared. The local name was also noted down. The collected specimens were preserved in 10% formalin. The water sample was sent to the Laboratory of Water and Sanitation Department, Mandalay City Development Committee (MCDC) for determination of physiochemical factors.

Species Identification

Identification of fishes species were made according to Day (1878), Jayaram (1981), Talwar and Jhingran (1991).

Data Analysis

Species richness, diversity and evenness of fish species were analyzed by Margalef (1958), Simpson (1949), Shannon-Wiener (1948), Hill (1973), and Ludwig (1988).

Species Richness (Margalef, 1958)

$$d = \frac{S - 1}{\ln(N)}$$

Where, d = Margalef's species richness index
 S = Number of species
 N = Total number of individuals

Simpson's Diversity Index (1949)

$$D = \frac{1}{S} \sum_{i=1}^S \frac{n_i(n_i - 1)}{n(n - 1)} \quad (\text{Simpson, 1949})$$

Where, Σ = sum
 D = Simpson's index of diversity
 S = number of species
 n_i = number of individuals in the i^{th} species
 n = total number of individuals of all species

Shannon-Wiener's Index (1948)

$$H' = \sum_{i=1}^S \left(\frac{n_i}{n}\right) \text{Ln} \left(\frac{n_i}{n}\right) \quad (\text{Shannon - Wiener, 1949})$$

Where, H' = index of species diversity
 S = number of species
 n_i = number of individuals in the i^{th} species in the sample
 n = total number individuals of all species in the sample

For Hill's diversity number (1973)

$$\text{Number 1: } N_1 = e^{H'}$$

Where, H' = Shannon's index

N_1 = number of abundant species in the sample

$$\text{Number 2: } N_2 = 1/D$$

Where, D = Simpson's index

N_2 = number of very abundant species in the sample

Evenness

Hill's ratio (1973).

$$E = \frac{(1/D) - 1}{e^{H'} - 1} = \frac{N_2 - 1}{N_1 - 1} \quad (\text{Hill, 1973})$$

Results

A total of 69803 individuals and 39 species confined to 27 genera, 16 families and eight orders were recorded from Nat Min Chaung In during the study period of July 2015 to January 2016 (Table 1).

Table 1. List fish species recorded from Nat Min Chaung In from July, 2015 to January , 2016

Discussion

In the present study, 39 species of fish with 69803 individuals confined to 27 genera, 16 families and eight orders were recorded. Based on the result of species composition, the Cypriniformes fishes (38.46%) was found to be the most dominant group during the study period. The present result agrees with Vijiaylaxmi and Vijaykumar(2011) who reported that family Cyprinidae was most dominant family in Karala River and Mullameri River respectively in India.

Mi Mi Lay (1993) recorded 57 species from Nat Min Chaung In. In her study, the family Cypriniformes is the most dominant. There is similar result in the present study. According to the present number of recorded species, the fish species are becoming reduced. It may be assumed that the result is due to illegal fishing activities, over exploitation, and degradation of aquatic environment caused by agriculture land and water use.

According to monthly data of present study, the highest value of species richness (d) was found in August. The highest value of Simpson's index diversity (D), Shannon-Wiener's index (H') and Hill number value N_1 , N_2 were found in November in the study period. The highest value of evenness index (E) was recorded in January. Similar result was also reported by Galibet *al.* (2013) who have recorded the value of diversity and richness indices of fish fauna that was higher in the winter months (November to February) than other months in Bangladesh.

Nath and Deka (2012) reported that the richest fish diversity is in winter. The lowest number of species was recorded in the month of June, this is due to heavy rain during this time which makes fishing very difficult as water level reached its maximum in Chandubi Tectonic Lake, India. In the present study, the lowest diversity indices were found in July. This is because water level reached its maximum on an account of heavy rain in this time and some species may be dispersed to other sites with the water current.

With respect to diversity indices, the number of each species per sample is a measure of richness. Simpson's diversity index is a measure of diversity. It takes into account the number of species present, as well as the abundance of each species. It is expressed as $1-D$ or $1/D$. The value which is standing for the dominance index is used in pollution monitoring studies, as D increases. That way it is effectively used in environmental impact assessment to identify perturbation (Khan, 2006).

Namin and Spurny (2004) reported that Shannon-Wiener index (H') is the value that combines species diversity and evenness where > 3.99 is considered as no impacted; 3.00-3.99, slightly impacted; 2.00-2.99, moderately impacted and < 2.00 , severely impacted. Based on this scale, the present study of (H') is categorized as moderately impacted in study area because H' value is within the range of 2.00-2.99.

The physiochemical characteristics of water have an important role in supporting fish diversity in freshwater ecosystems (Basavarajaet *al.*, 2014).Swekeet *al.* (2013) recorded that the human activities may influence fish diversity but its variations also could be because of the differences in food availability, habitat preference of fish, breeding sites, depth, topography and physiochemical properties of water.

Temperature in the range 20°C to 32°C is ideal for majority of freshwater fishes (Boyd, 1990). Kundanagaret *al.* (1996) reported that the natural bodies of water may exhibit a seasonal and during variation and is closely related with the change in atmospheric temperature.

In the present study, the lowest water temperature was 21.4°C in December and the highest water temperature was 32.5°C in July. This result showed that the temperature value range influences fish species for richness, abundance and survival.

The pH of an aquatic ecosystem is important because it is closely linked to biological productivity (UNEP, 2006). According to FAO/NACA, 2003, the range of pH value, 7.0 to 8.5 is considered to support a rich biota and fish. In the study period, the pH values varied between 7.4 and 8.2. Thus, this optimal pH value is ideal for fish species in the study area.

According to Santosh and Shrihari (2008), dissolved oxygen (DO) is a primary and comprehensive indicator of water quality in surface water. The decline of DO level has serious implication for the health of aquatic system. The optimum value for good water quality is 4 mg/L to 6 mg/L of DO, which ensures healthy aquatic, live in a water body. DO > 5 mg/L is stressful to most aquatic organisms, which DO < 2 mg/L does not support fish life (EPA, 2003).

In the present study, the recorded DO value range from 3.8 mg/L to 6.8 mg/L which is a safe level to support fish life. According to relationship monthly number of individuals fish and physiochemical parameter, the maximum number of individuals were found in December. Therefore, the present study may be assumed that there is a good relationship between monthly occurrence of fish species and individuals with physiochemical parameters. So, water depth, dissolved oxygen and pH were found to be the most important variables in shaping fish assemblage. The present study indicates that the water body of Nat Min Chaung In is rich in diversified fish fauna due to the optimal water quality for fish survival.

Conclusion

Nat Min Chaung In is a seasonal flood plain leasable fishery which supports the people inhabitants of the surrounding area for their livelihoods. The present study focused on fish species richness and diversity of Nat Min Chaung In. These results show that the biodiversity measure may be appropriate indicator for monitoring sustainability in fisheries. Understanding the physiochemical factors that influence fish community structure is important not only for accumulating basic information but also to predict the effects of environmental change on the Nat Min Chaung In will help in implementing the future conservation activities and maintaining of fish species in that area.

Acknowledgements

We are greatly indebted to Dr Thein Win, Director General, Department of Higher Education, Ministry of Education, Dr Kay Thi Tin, Dr Myin Zu Minn and, Dr Mi Mi Gyi, Pro-rectors, and Dr Thant Zin, Professor and Head, and Dr San San Myint and Dr Moe Kyi Han, Professors, Zoology Department, University of Mandalay for their encouragement.
